THE THRESHOLD FOR PERSISTENCE OF PARASITES WITH MULTIPLE INFECTIONS

Abstract. We analyse a model for macro-parasites in an age-structured host population, with infections of hosts occurring in clumps of parasites. The resulting model is an infinite system of partial differential equations of the first order, with non-local boundary conditions. We establish a condition for the parasite-free equilibrium to be asymptotically stable, in terms of $R_0 < 1$, where $R_0$ is a quantity interpreted as the reproduction number of parasites. To show this, we prove that $s(B - A) < 0 \ (\geq 0)$ if and only if $\rho(B(A)^{-1}) < 1 \ (\geq 1)$, where $B$ is a positive operator, and $A$ generates a positive semigroup of negative type. Finally, we discuss how $R_0$ depends on the parameters of the system, especially on the mean size of infecting clumps.

1. Introduction. A basic concept in models for micro-parasites (bacteria, viruses, ...) is the basic reproductive number $R_0$, the expected number of infected hosts produced by a single infected host in a completely susceptible host population [7]: in fact, in most epidemic models, $R_0 > 1$ is a necessary and sufficient condition for the instability of the disease-free equilibrium, and a sufficient condition for the persistence of pathogens.

A similar concept (see, for instance, [24]) has been introduced in several models for macro-parasites (mainly helminths), but it has been difficult to obtain general results, because the basic models for macro-parasites consist of an infinite system of differential equations, whose first root can be traced to Kostizin [15]. Such systems have proved very difficult to analyse (see, however, [10, 17, 18, 22, 23, 20]) and much of the analysis, including the formulation of thresholds for parasite persistence in terms of $R_0$, has been performed using simplified models consisting of few ordinary differential equations.

Anderson and May [1] introduced in the infinite model by Kostizin the assumption that parasite distributions were, at each time, negative binomial, obtaining simplified models consisting of few ordinary differential equations. The negative binomial distribution has been routinely used to fit empirical data on parasite

abundance, and is considered an aggregated (or overdispersed) distribution, meaning that, if parasites are distributed among hosts in a negative binomial fashion, most parasites will be aggregated in few hosts. Generally, the negative binomial is parametrized with a positive parameter \( \kappa \) that measures the degree of aggregation. \( \kappa \), was used as a fixed constant in the model by Anderson and May [1], and in many later applications (see [4, 26] for recent reviews). It has been found that parasite persistence occurs in this model if

\[
R_0 := \frac{bK}{e + K} \cdot \frac{1}{\mu + \alpha + \sigma} > 1. \tag{1}
\]

This threshold is independent of the value of the aggregation parameter \( \kappa \).

While the model by Anderson and May has been extremely influential in understanding the dynamics of host-parasite systems, it is certainly not satisfactory in several respects. First of all, the assumption of a negative binomial distribution is inconsistent with the (infinite) system of differential equations where it is inserted; second, the assumption of a fixed \( \kappa \) is in contrast with empirical observations [12] of variability of \( \kappa \) in space and time; finally, assuming a fixed aggregation index \( \kappa \) does not make it possible to understand out of which mechanisms aggregation arises. Thus, progress has been made in several directions, be it analysing directly the infinite system, considering other types of low-dimensional approximations [19], or introducing in the model those biological features that may cause parasite aggregation: host heterogeneity and ‘clumped’ infections have been considered especially relevant in this respect [25].

This paper presents the analysis of the infinite system with the latter feature: ‘clumped’ infections. By ‘clumped infections’, we mean that a host gets infected with a ‘parcel’ of larvae at the same time. This feature has already been considered in models aimed at characterizing the age-intensity of parasitism among hosts [14], and in dynamic models at the population level [21]. It was found [21] in the analysis of a three-dimensional approximation of the infinite model that (1) is correct only when infections occur only with a single parasite; otherwise, \( R_0 \) can be expressed only implicitly, but it can be seen that the value of \( R_0 \) decreases as aggregation is increased, in contrast to (1), found with fixed aggregation [1].

It seems therefore interesting understanding how \( R_0 \) depends on the level of aggregation in the infinite model, in order to see whether the result of [21] depends on the approximation used. A rigorous treatment of the threshold condition for parasite persistence, written as \( R_0 > 1 \), has been carried out, using semigroup methods, in [23] (see also [20] for extensions of the idea). The computations performed in [23], while providing the general setting used here, did not yield an explicit expression for the case considered here.

The organization of the paper is as follows. In Section 2 we present the model, set it in abstract form, and, summarizing some results of [22, 23], show (Proposition 2) that the parasite-free-equilibrium is asymptotically stable or unstable, according to whether \( s(B + A) \) is negative or positive, where \( B \) and \( A \) are suitable operators, and \( s \) represents the spectral bound [28]. In Section 3, we prove, in an infinite-dimensional setting, a technical lemma on the spectrum of positive operators, well known in finite dimensions [7]: i.e. that \( s(B + A) < 0 \) [\( > 0 \)] if and only if \( \rho(B(-A)^{-1}) < 1 \) [\( > 1 \)] under suitable assumptions on \( A \) and \( B \); such a result is somehow alluded to in the infinite-dimensional definition of \( R_0 \) [11], but we could not find in the literature any explicit statement, or proof. Finally, in Section 4 we compute explicitly \( R_0 = \rho(B(-A)^{-1}) \), and discuss the biological interpretation of the result.
2. The model, and its abstract setting. The variables of the model are \( p_i(t) \) for \( i \geq 0 \), the density of hosts carrying \( i \) parasites at time \( t \). One can write differential equations for these variables, by taking into account the new infections, the deaths of adult parasites, as well as hosts’ births and deaths. The method is explained, for instance, in [23]; the main difference lies in the infection mechanism.

Here, we assume that, as a host is infected, it ingests an infecting “parcel”, of which \( c_l \) represents the probability that it consists of \( l \) larvae, \( l \geq 1 \); the mean number of larvae in an infecting “packet” is \( \gamma = \sum_{l=1}^{\infty} l c_l < +\infty \). Finally, we assume that \( \varphi \) is the rate at which a host ingests an infective parcel.

Under this assumption on the infection process together with constant rates of parasite death \( \sigma \), of host birth \( b \) and death \( d \), plus parasite-induced host death rate \( \alpha \) and birth reduction \( \xi \), one obtains the following infinite system of differential equations

\[
\begin{aligned}
\frac{d}{dt}p_0(t) &= -(\mu + \varphi(t))p_0(t) + \sigma p_1(t) + b \sum_{i=0}^{+\infty} p_i(t) \xi^i \\
\frac{d}{dt}p_i(t) &= -(\mu + \varphi + i(\alpha + \sigma))p_i(t) + \sigma(i+1)p_{i+1}(t) \\
&+ \varphi \sum_{l=1}^{1} c_l p_{i-l}(t) \quad i \geq 1.
\end{aligned}
\]

We showed in [23] that including hosts’ age in the model (as in [17]) does not really introduce big complications, and indeed makes many expressions more transparent. Thus, we rewrite the model for an age-structured host population, allowing for age-dependent host fertility and mortality, and, in order to have a parasite-free equilibrium, for density-dependent host birth rate.

Thus, the model we consider in the paper is

\[
\begin{aligned}
\frac{\partial}{\partial t} p_i(a, t) + \frac{\partial}{\partial a} p_i(a, t) &= -(\mu(a) + \varphi(t) + i(\alpha + \sigma))p_i(a, t) \\
&+ \sigma(i+1)p_{i+1}(a, t) + \varphi(t) \sum_{l=1}^{i} c_l p_{i-l}(a, t), \quad i \geq 0, \\
p_0(0, t) &= \psi(N(t)) \int_{0}^{+\infty} \beta(a) \sum_{i=0}^{+\infty} p_i(a, t) \xi^i \ da, \\
p_i(0, t) &= 0, \quad i > 0, \\
p_i(a, 0) &= h_i(a), \quad i \geq 0,
\end{aligned}
\]

with the convention \( p_{-1}(a, t) \equiv 0 \). Here \( p_i(a, t) \) for \( i \geq 0 \) and \( a \) in \([0, +\infty)\) denotes the density of hosts of age \( a \) harbouring \( i \) parasites at time \( t \).

Here \( N(t) \) is total host population size, and \( P(t) \) [to be used below] is total parasite population size, given by

\[
N(t) = \int_{0}^{+\infty} \sum_{i=0}^{+\infty} p_i(a, t) \ da \quad \text{and} \quad P(t) = \int_{0}^{+\infty} \sum_{i=1}^{+\infty} i p_i(a, t) \ da.
\]
Moreover, the infection rate $\varphi(t)$, is given, following the time-scale argument of Anderson and May [1] about free-living larvae, by

$$\varphi(t) = \frac{hP(t)}{c + N(t)}.$$  \hspace{1cm} (5)

As for demographic parameters, $\mu(a)$ is the natural death rate of hosts while the fertility rate of hosts carrying $i$ parasites is given by $\psi(N(t))\beta(a)\xi_i$, where $\beta$ is the maximum fertility rate, and $\psi$ is a decreasing function that shapes the density-dependence of fertility.

Following standard assumptions in the theory of age-structured populations [13, 28], we assume that $\beta$ and $\mu$ are nonnegative functions, $\beta \in L^\infty[0, +\infty)$, there exist $\mu_-, \mu_+$ such that $0 < \mu_- \leq \mu(a) \leq \mu_+$ for a.e. $a \in [0, +\infty)$. As for the function $\psi$, we assume $\psi \in C^1([0, +\infty))$, $\psi(0) = 1$, $\psi'(s) < 0$, $\lim_{s \to +\infty} \psi(s) = 0$.

The behaviour of the purely demographic system ($h_i \equiv 0, c_i = 0$ for $i \geq 1$) is well known. Let

$$\pi(a) = \exp\{-\int_0^a \mu(s) \, ds\} \text{ (survival function)}$$

and

$$\mathcal{R} = \int_0^{+\infty} \beta(a) \pi(a) \, da.$$ 

It can be easily seen that, if $\mathcal{R} > 1$, there is a stationary solution $\bar{p}$ of (3) given by

$$\begin{cases} 
\bar{p}_0(a) = \frac{K}{\int_0^{+\infty} \pi(u) \, du} \pi(a), \\
\bar{p}_i(a) = 0, & i > 0.
\end{cases} \hspace{1cm} (6)$$

This will be called the ‘Parasite Free Equilibrium’, shortly PFE.

It is well known [13, 28] that $\bar{p}_0$ will be locally asymptotically stable for the purely demographic system if and only if there are no solutions with Re $\lambda \geq 0$ of

$$\frac{1}{\mathcal{R}} \int_0^\infty \beta(a)\pi(a)e^{-\lambda a} \, da + \frac{\psi'(K)KR}{\mathcal{R}} \int_0^\infty \pi(a) e^{-\lambda a} \, da = 1.$$ 

All these conditions on the demographic functions will be implicitly assumed from here onwards.

In order to study the stability of the equilibrium $\bar{p}$ of (3), we follow the abstract approach described in [22] using semigroup theory. To perform this study, we transform system (3) into the abstract Cauchy problem:

$$\begin{cases} 
p'(t) = A(p(t) + H(p(t)) + F(p(t)), \\
p(0) = p^0,
\end{cases} \hspace{1cm} (7)$$

where $A$ is the generator of a $C_0$-semigroup on a certain Banach space $X$, while $F : X \to X$ and $H : X \to F_A$ are locally Lipschitz operators.

Here $F_A$ is the Favard class of $A$ (see [2]). We recall the following general Theorem presented in (see [6] for details):

**Theorem A** ([22, 6]). Assume

$(\mathcal{H}_1)$ $A : D(A) \subset X \to X$ is the generator of a $C_0$-semigroup on a Banach space $X$,
(H2) $H : X \to F_A$ and $F : X \to X$ are locally Lipschitz continuous, i.e. for all $R > 0$ there exists $L_R$, $K_R > 0$ such that
\[ \|H(p) - H(q)\|_{F_A} \leq L_R \|p - q\|, \quad \|F(p) - F(q)\| \leq K_R \|p - q\| \]
for all $p, q \in X$ such that $\|p\|, \|q\| \leq R$ (more generally, $H$ and $F$ could be defined only on an open set of $X$).

Then,

(a) for each $p^0 \in X$ there exists a unique (local) mild solution of (7), i.e. a continuous function $t \to p(t)$ satisfying the integral equation
\[ p(t) = e^{tA}p^0 + A \int_0^t e^{(t-s)A}H(p(s))ds + \int_0^t e^{(t-s)A}F(p(s))ds; \]

(b) If $H$ and $F$ are continuously differentiable and $(p^0 + H(p^0)) \in D(A)$ then $p(t)$ is a classical solution of (7), i.e. $p(t) + H(p(t)) \in D(A)$ for each $t \in [0, t_{\max})$, $p(t)$ is differentiable and satisfies the equation (7) for each $0 \leq t < t_{\max}$.

(c) The mild solution depends continuously on the initial datum and gives rise to a nonlinear semigroup $T(t)$.

To use this “abstract approach” for system (7), we choose:

$$ X := \left\{ p = (p_i)_{i \in \mathbb{N}} : p_i \in L^1(0, \infty) \forall i \geq 0, \sum_{i=1}^{+\infty} i \int_0^{+\infty} |p_i(a)|da < \infty \right\}, $$

endowed with the norm
\[ \|p\| := \int_0^{+\infty} |p_0(a)|da + \sum_{i=1}^{+\infty} i \int_0^{+\infty} |p_i(a)|da. \]

As for the operators $A$, $F$ and $H$, we let $A$ be the closure of the (closable) linear operator $A$ on $X$ defined by
\[ D(A) = \left\{ p = (p_i)_{i \in \mathbb{N}} : p_i \in W^{1,1}(0, \infty), p_i(0) = 0 \forall i \geq 0, \quad \exists N \in \mathbb{N} \text{ s.t. } p_i \equiv 0 \forall i > N \right\}, \]

\[ A p_i(a) := -p'_i(a) - (\mu(a) + i(\alpha + \sigma))p_i(a) + (i + 1)\sigma p_{i+1}(a) \quad \text{for } i \geq 0. \]

$F$ is the nonlinear operator given by
\[ (Fp)_0(a) = \frac{-h \sum_{i=1}^{+\infty} i \int_0^{+\infty} p_i(s)ds}{c + \sum_{i=0}^{+\infty} \int_0^{+\infty} p_i(s)ds} p_0(a), \]
\[ (Fp)_i(a) = \frac{-h \sum_{i=1}^{+\infty} i \int_0^{+\infty} p_i(s)ds}{c + \sum_{i=0}^{+\infty} \int_0^{+\infty} p_i(s)ds} \left( \sum_{j=1}^{i} c_j p_{i-j}(a) - p_i(a) \right) \quad \text{i \geq 1}. \]

$F$ is defined on $E$ where
\[ E := \{ p \in X : c + \sum_{i=0}^{+\infty} \int_0^{+\infty} p_i(s)ds \neq 0 \}. \]
Finally, $H$ is
\[(Hp)_0(a) = -\psi \left( \int_0^\infty \sum_{i=0}^{+\infty} p_i(s)ds \right) \left( \int_0^\infty \beta(s) \sum_{i=0}^{+\infty} p_i(s)\xi^i ds \right) \pi(a), \tag{9} \]
\[(Hp)_i(a) \equiv 0, \quad \text{for } i \geq 1. \]

In order to study the stability of $p^\ast$, we will use the linearization principle, proved in [5] for nonlinear semigroups, and specialized to equations of the type (7) in [23].

Before stating the precise theorem, we recall some standard notations and results about the spectrum of generators of semigroups (see, for instance, [9] or [28]). Let $A : D(A) \subset X \rightarrow X$ be the generator of a $C_0$-semigroup $T(t)$ on a Banach space $X$; then, one can define the quantities:

- $s(A) := \sup \{ \text{Re} \lambda : \lambda \text{ is an eigenvalue of } A \}$, the spectral bound of $A$.
- $\rho(A) := \sup \{ |\lambda| : \lambda \text{ is an eigenvalue of } A \}$, the spectral radius of $A$.
- $\omega(A) := \lim_{t \rightarrow -\infty} \frac{1}{t} \log \| T(t) \|$, the type or growth bound of $T(t)$.
- $\omega_1(A) := \lim_{t \rightarrow -\infty} \frac{1}{t} \log \alpha$, where $\alpha$ is the measure of noncompactness.

It is well known [28, Prop. 4.13] that $\omega_0(A) = \max(\omega_1(A), s(A))$.

For an equilibrium $p^\ast$ of (7), define the linear operator $B_{p^\ast} : = A(I + H'(p^\ast))p + F'(p^\ast)p$. The type of the semigroup generated by $B_{p^\ast}$ determines the stability of $p^\ast$:

**Theorem B** ([23, Corollary 1]). If $\omega_0(B_{p^\ast}) < 0$, then $p^\ast$ is exponentially asymptotically stable for (7). If $\omega_0(B_{p^\ast}) > 0$, $X = X_1 \oplus X_2$ with $X_1$ finite dimensional, $X_2$ invariant with respect to $e^{tB_{p^\ast}}$ for $i = 1, 2$, and

\[ \min \{ \text{Re} \lambda : \lambda \in \sigma(B_{p^\ast} | X_2) \} > \max \{ \omega_0(B_{p^\ast} | X_2), 0 \} \]

then $p^\ast$ is unstable for (7).

In order to apply Theorem B to the equilibrium $\bar{p}$ of (3), we need first to linearize $H$ and $F$. We can easily establish the following:

**Lemma 2.1.** Let $c_i \geq 0$, $i \geq 1$ and $\sum_{i=1}^{+\infty} c_i = 1$. The Fréchet derivatives of $F$ and $H$ at $\bar{p}$ are given by:

\[
\left[ F'(\bar{p})u \right]_0(a) = -\frac{h}{c + K} \frac{\pi(a)}{\int_0^{+\infty} \pi(u) du} \sum_{i=1}^{+\infty} i \int_0^{+\infty} u_i(s) ds,
\]

\[
\left[ F'(\bar{p})u \right]_i(a) = \frac{c_i h}{c + K} \frac{\pi(a)}{\int_0^{+\infty} \pi(u) du} \sum_{i=1}^{+\infty} i \int_0^{+\infty} u_i(s) ds, \quad i \geq 1,
\]

\[
\left[ H'(\bar{p})u \right]_0(a) = -\left. \frac{\psi'(K)K}{\pi(u) du} \sum_{i=0}^{+\infty} \int_0^{+\infty} u_i(s) ds \right|_{\beta(s) \sum_{i=1}^{+\infty} i u_i(s) \xi^i ds} \pi(a),
\]

\[
\left[ H'(\bar{p})u \right]_i(a) = 0, \quad i \geq 1.
\]

Note that these operators differ from those obtained in [23] only in the components $[F'(\bar{p})u]_i$, $i \geq 1$. Indeed, if $c_1 = 1$ and $c_i = 0$ for $i > 1$ (infections with a single parasite), we recover exactly the results in [23].
Because of the structure of $H'(\tilde{p})$ (all components beyond the 0-th are 0), the following proposition is useful to determine the type of the semigroup generated by $B(\tilde{p})$:

**Theorem C** ([23, Theorem 3]). Let $A_0$ and $B_1$ be the generators of $C_0$-semigroups on the Banach spaces $Y_0$ and $Y_1$ respectively. Let $H_i \in \mathcal{L}(Y_i, F_{A_0})$ for $i = 0, 1$ and $B_{10} \in \mathcal{L}(Y_0, Y_0)$. Then:

(i) The operator $\tilde{B}$ defined by:

$$\tilde{B}\begin{pmatrix} q_0 \\ q_1 \end{pmatrix} = \begin{pmatrix} A_0(q_0 + H_0 q_0 + H_1 q_1) + B_{10} q_1 \\ B_1 q_1 \end{pmatrix}$$

is the generator of a $C_0$-semigroup on $Y = Y_0 \oplus Y_1$;

(ii) If, letting $I_0$ be the identity in $Y_0$,

$$(I_0 + H_0)$$

is invertible on $Y_0$,

then

$$\omega_0(B_1) < 0 \quad \text{and} \quad \omega_0(A_0(I_0 + H_0)) < 0 \iff \omega_0(\tilde{B}) < 0.$$ 

We now show that Theorem C can be applied to $\tilde{B} := B_p$.

Set

$$\check{X}_1 = \{ \check{q}_1 = (q_i)_{i \geq 1} : q_i \in L^1(0, +\infty), \sum_{i=1}^{+\infty} \int_0^{+\infty} i q_i(a) |da| < \infty \},$$

$$X_0 = X_1 = L^1(0, +\infty) \quad \text{and} \quad X = X_0 \oplus \check{X}_1.$$ 

The operator $\tilde{B}$ can be represented as

$$\tilde{B}\begin{pmatrix} q_0 \\ q_1 \end{pmatrix} = \begin{pmatrix} A_0(q_0 + H_0 q_0 + H_1 q_1) + B_{10} q_1 \\ B_1 q_1 \end{pmatrix},$$

where

- $A_0 : D(A_0) = \{q_0 \in X_0 : q_0 \in W^{1, 1}(0, \infty), q_0(0) = 0 \} \to X_0$,

- $A_{00} q_0(a) = -q_0'(a) - \mu(a) q_0(a)$;

- $B_{10} : \check{X}_1 \to X_0$,

- $B_{10} \check{q}_1(a) = -h \sum_{i=1}^{+\infty} i \int_0^{+\infty} q_i(s) ds + \sigma q_1(a)$;

- $H_0 : X_0 \to F_{A_0}$,

- $H_0 q_0(a) = -\left( \frac{\psi'(K) K R}{\int_0^{+\infty} \pi(u) du} \int_0^{+\infty} q_0(s) ds + \frac{1}{R} \int_0^{+\infty} \beta(s) q_0(s) ds \right) \pi(a)$;

- $H_1 : X_1 \to F_{A_0}$,

- $H_1 \check{q}_1(a) = -\left( \frac{\psi'(K) K R}{\int_0^{+\infty} \pi(u) du} \sum_{i=1}^{+\infty} \int_0^{+\infty} q_i(s) ds + \frac{1}{R} \int_0^{+\infty} \beta(s) \sum_{i=1}^{+\infty} q_i(s) \xi^i ds \right) \pi(a)$.

$B_1$ is the closure of

$$B_1 : D(B_1) \to \check{X}_1, \quad B_1 = B + A_1.$$
with
\[ A_1 : D(A_1) \to X_1, \]
\[ D(A_1) = \left\{ \tilde{q}_i \in X_1 : q_i \in W^{1,1}(0, +\infty), q_i(0) = 0 \ \forall \ i \geq 1, \right. \]
\[ \left. \exists N \in \mathbb{N} \text{ s.t. } p_i \equiv 0 \ \forall \ i > N \right\} \tag{10} \]
\[ A_1 q_i(a) = -q'_i(a) + (\mu(a) + i(\alpha + \sigma)q_i(a) + \sigma(i + 1)q_{i+1}, \ i \geq 1, \]
and
\[ B : \bar{X}_1 \to \bar{X}_1, \]
\[ B\tilde{q}_i(a) = b\varphi(\tilde{q}_i), \text{ with } b(\in X_1) = (c_1, c_2, \ldots)\pi(a), \]
\[ \varphi(q) = \frac{bK}{(c + K)L} \sum_{i=1}^{\infty} \int_{0}^{+\infty} q_i(s)ds. \tag{11} \]

**Proposition 1.** The closure \( \bar{A}_1 \) of \( A_1 \) generates a \( C_0 \)-semigroup on \( \bar{X}_1 \), with \( \omega_0(\bar{A}_1) < 0 \). The closure of \( B_1 \) generates a \( C_0 \)-semigroup on \( \bar{X}_1 \).

**Proof.** To see that \( \bar{A}_1 \) generates a \( C_0 \)-semigroup on \( \bar{X}_1 \) with \( \omega_0(\bar{A}_1) < 0 \), one can follow the proof given for the operator \( A \) in [22].

Since \( B \) is bounded, the classical result on bounded perturbations can be applied and \( \bar{B}_1 = \bar{A}_1 + B \) generates a \( C_0 \)-semigroup.

**Proposition D** ([23, Prop. 5 and 6]). \( I_0 + H_0 \) has a bounded inverse on \( X_0 \), and \( \omega_0(A_0(I_0 + H_0)) < 0 \).

Summarizing the results of this Section, we have the following

**Proposition 2.** The equilibrium \( \bar{p} \) of (3) is asymptotically stable [unstable] if \( \omega_0(\bar{A}_1 + B) < [>] 0 \), with \( A_1 \) and \( B \) defined in (10) and (11).

3. \( s(B + A) < 0 \iff \rho(B(-A)^{-1}) < 1 \). It is well known that, in most epidemic models, stability [or instability] of the disease-free equilibrium holds if \( R_0 < 1 \) [\( > 1 \)], where \( R_0 \) represents the average number of infectious produced by a single infected over its infectious period. Diekmann and Heesterbeek [7] have given a general definition of \( R_0 \) in terms of the spectral radius of a positive operator. In [8] they show, in a finite dimensional context, the equivalence between \( R_0 < 1 \) and the stability of the disease-free equilibrium, by proving the following

**Proposition E.** Let \( B \) be a nonnegative irreducible matrix, and \( D \) an invertible matrix with nonnegative inverse. Then

\[ s(B - D) < 0 \iff \rho(BD^{-1}) < 1. \]

In most applications, the variables indicate different infectious stages, \( D \) describes the transitions between stages (in many cases, \( D \) is a diagonal matrix whose entries are the exit rates from the infective classes) and \( B \) represents the infection process.

In this Section, we give an extension of Proposition E to the infinite-dimensional case that can be applied to Proposition 2. Heesterbeek [11] gives a definition of \( R_0 \) in an infinite-dimensional case, but we could not find in the literature any explicit statement, or proof, of a result analogous to Proposition E in infinite dimensions.

Our proof is completely analogous to that in [8], but, first, we need the following:
Lemma 3.1. Let $C$ be a linear, compact, positive operator on a Banach space $X$, with total positive cone $X^+$ (i.e., its linear hull is dense in $X$). If $C$ has a spectral radius $\rho > 0$, then $\rho$ is a pole of the resolvent of maximal order on the spectral circle, with an eigenvector in $X^+$.

Proof. See [27, Appendix 2.A, Corollary].

Our result is the following

**Proposition 3.** Let $A$ and $K$ be operators on a Banach space $X$ with total positive cone $X^+$. Assume that

H1) $A$ is the generator of a positive strongly continuous semigroup with $\omega_0(A) < 0$.

Hence there exists $(-A)^{-1}$ and $(-A)^{-1} = \int_0^{\infty} e^{tA} dt \geq 0$ (see [9, Cap. VI, Lemma 1.9 for details]).

H2) $K$ is a linear, compact, positive operator.

Then, the following are equivalent:

(a) $s(A + K) < 0$,
(b) $\rho(K(-A)^{-1}) < 1$.

Proof. (a) $\Rightarrow$ (b): Since $K$ is compact, $\omega_1(A + K) = \omega_1(A)$ [28, Proposition 4.14]. Therefore, from (1), $\omega(A + K) = \omega_1(A) \leq \omega_0(A) < 0$ and, from this and (a),

$$\omega_0(A + K) = \max(s(A + K), \omega_1(A + K)) < 0. \quad (12)$$

Since $A + K$ generates a strongly positive semigroup, Lemma VI.1.9 of [9] can be applied to the semigroup generated by $A + K$ and we have from (12) $[-(A + K)]^{-1} \geq 0$. From H1) and H2) it follows that the operator $K(-A)^{-1}$ is compact and positive.

Therefore, $\rho(K(-A)^{-1}) \in \sigma(K(-A)^{-1})$ [3, Prop. A 3.12].

If $\rho(K(-A)^{-1}) = 0$, (b) is true. Then, assume $\rho(K(-A)^{-1}) > 0$; by virtue of Lemma 3.1, there exists a positive eigenvector $\varphi$ that corresponds to $\rho(K(-A)^{-1})$.

From $K(-A)^{-1} \varphi = \rho(K(-A)^{-1}) \varphi$ it follows that

$$(K(-A)^{-1} - I) \varphi = (\rho(K(-A)^{-1}) - 1) \varphi$$

and letting $\psi = (-A)^{-1} \varphi$, this identity becomes

$$K \psi + A \psi = (\rho(K(-A)^{-1}) - 1) \varphi. \quad (13)$$

Applying $[-(A + K)]^{-1}$ to this identity, we have

$$-\psi = (-A - K)^{-1} (\rho(K(-A)^{-1}) - 1) \varphi.$$

Since $-\psi \leq 0$, it follows that $\rho(K(-A)^{-1}) - 1 \leq 0$, that is

$$\rho(K(-A)^{-1}) \leq 1.$$

If $\rho(K(-A)^{-1}) = 1$, (13) becomes $K \psi + A \psi = 0$ which contradicts (a). This concludes the proof of (b).

(b) $\Rightarrow$ (a) We show at first that $s(K(-A)^{-1} - I) \leq \rho(K(-A)^{-1}) - 1$. To prove this, let $\lambda$ be an eigenvalue of $K(-A)^{-1} - I$, that corresponds to the eigenvector $v$, then $K(-A)^{-1} v - v = \lambda v$, therefore $K(-A)^{-1} v = (\lambda + 1) v$ and $|\lambda + 1| \leq \rho(K(-A)^{-1})$; from this it easily follows that $\Re \lambda \leq \rho(K(-A)^{-1}) - 1$ and therefore

$$s(K(-A)^{-1} - I) \leq \rho(K(-A)^{-1}) - 1.$$

From H1) and (2) $K(-A)^{-1}$ is linear, positive, and continuous. Therefore, it generates a strongly positive continuous semigroup and $0 \in \rho(K(-A)^{-1} - I)$. Then
Lemma 1.9, Cap.VI of [9] can be applied to $K(-A)^{-1}$ and since $s(K(-A)^{-1} - I) < 0$, we get $[-(K(-A)^{-1} - I)]^{-1} \geq 0$. Therefore, since $(-A)^{-1} \geq 0$,

$$[-(K(-A)^{-1} + I)(-A)]^{-1} = (-A)^{-1}[-(K(-A)^{-1} - I)]^{-1} \geq 0$$

and

$$[(K(-A)^{-1} + I)(-A)]^{-1} = (-K - A)^{-1} \geq 0.$$  

Then Lemma 1.9, Cap.VI of [9] can be applied to $A + K$ and we conclude that $s(A + K) < 0$. \hfill \square

4. The threshold for the stability of the parasite–free equilibrium. By Proposition 2, we know that $\bar{p}$ is asymptotically stable if $\omega(B + \overrightarrow{A}_1) < 0$. From the previous Section, we have

**Proposition 4.** $s(B + \overrightarrow{A}_1) < 0 \iff \rho(B(-\overrightarrow{A}_1)^{-1}) < 1$.

**Proof.** By virtue of Proposition 1, $\overrightarrow{A}_1$ verifies $H1$) of Proposition 3; $B$ is a linear, compact (with one-dimensional range), positive operator, satisfying $H2)$ of Proposition 3. Moreover $L^1_+$ is a total cone in $L^1$. Therefore, the thesis follows from Proposition 3. \hfill \square

**Theorem 4.1.** The equilibrium $\bar{p}$ of (3) is asymptotically stable if $R_0 < 1$ and unstable if $R_0 > 1$, where

$$R_0 = \rho(B(-\overrightarrow{A}_1)^{-1})$$

$$= \frac{hK}{(c + K)L} \int_0^\infty e^{(-\alpha+\sigma)s} G\left(\frac{\sigma}{\alpha + \sigma} + \frac{s}{\alpha + \sigma} e^{(-\alpha+\sigma)s}\right) ds, \quad (14)$$

and $G(z) := \sum_{i=1}^{+\infty} c_i z^i$.

**Proof.** By Proposition 4, $s(B + \overrightarrow{A}_1) < 0 \iff \rho(B(-\overrightarrow{A}_1)^{-1}) < 1$. Moreover, $\omega_1(\overrightarrow{A}_1 + B) = \omega_1(A_1)$ since $B$ is compact ([28], Prop. 4.14) and $\omega_1(\overrightarrow{A}_1) < 0$ (Proposition 1); therefore, $\omega_0(B_1) < 0$ if and only if $\rho(B(-\overrightarrow{A}_1)^{-1}) < 1$.

We now show that $\rho(B(-\overrightarrow{A}_1)^{-1})$ is given by the expression (14).

In fact, let $\rho$ be an eigenvalue and $q$ an eigenvector of $B(-A_1)^{-1}$, that is

$$B(-A_1)^{-1}q = \rho q.$$  

(15)

By the definition (11) of $B$ we have $B(-\overrightarrow{A}_1)^{-1}q = b\varphi((-\overrightarrow{A}_1)^{-1}q)$. Then in (15) we can set $q = b$ so that necessarily $\rho = \varphi((-\overrightarrow{A}_1)^{-1}b)$. This means that $\rho(B(-\overrightarrow{A}_1)^{-1}) = \varphi(p)$ with $p := (-A_1)^{-1}b$.

We need only to compute $\varphi(p)$. By definition, $b = -\overrightarrow{A}_1 p$, i.e.

$$b + \overrightarrow{A}_1 p = 0.$$  

(16)

Using $b_i = c_i \pi(a)$ for $i \geq 1$, (16) becomes,

$$\begin{cases}
-p'(a) = (\mu(a) + i(\alpha + \sigma))p_1(a) + \sigma(i + 1)p_{i+1}(a) + c_i \pi(a) = 0, \\
p_i(0) = 0.
\end{cases}$$

(17)

If we set $q_i := \frac{p_i(a)}{\pi(a)}$, the first equation of (17) becomes

$$q'_i(a) = -i(\alpha + \sigma)q_i(a) + \sigma(i + 1)q_{i+1}(a) + c_i \quad \text{for} \quad i \geq 1.$$  

(18)
Multiplying (18) by $z^i$ and summing for $i$ from 0 to $+\infty$ (for $i = 0$, we can set $c_0 = 0$ so that $q'_0 = \sigma q_1$) we get

$$\sum_{i=0}^{+\infty} q'_i(a)z^i = -\sum_{i=0}^{+\infty} i(\alpha + \sigma)q_i(a)z^i + \sum_{i=0}^{+\infty} \sigma(i + 1)q_{i+1}(a)z^i + \sum_{i=0}^{+\infty} c_iz^i. \quad (19)$$

Setting

$$Q(a, z) := \sum_{i=0}^{+\infty} q_i(a)z^i,$$

(19) can be rewritten as

$$\begin{cases}
Q_a(a, z) = (\sigma - (\alpha + \sigma)z)Q_z(a, z) + G(z), \\
Q(0, z) = 0.
\end{cases} \quad (20)$$

We can then obtain

$$\varphi(p) = \frac{hK}{(e + K)L} \int_0^{+\infty} \sum_{i=1}^{+\infty} ip_i(a)da = \frac{hK}{(e + K)L} \int_0^{+\infty} \pi(a) \sum_{i=1}^{+\infty} iq_i(a)da$$

$$= \frac{hK}{(e + K)L} \int_0^{+\infty} \pi(a)Q_z(a, 1)da. \quad (21)$$

The solution of (20) is

$$Q(a, z) = \int_0^a G \left( e^{-(\alpha+\sigma)(a-s)}z + \frac{\sigma}{\alpha + \sigma}(1 - e^{-(\alpha+\sigma)(a-s)}) \right) ds. \quad (22)$$

Substituting (22) in (21), we obtain

$$\varphi(p) = \frac{hK}{(e + K)L} \int_0^{+\infty} \pi(a)da \int_0^a e^{-(\alpha+\sigma)(a-s)}$$

$$\times G' \left( e^{-(\alpha+\sigma)(a-s)} + \frac{\sigma}{\alpha + \sigma}(1 - e^{-(\alpha+\sigma)(a-s)}) \right) ds$$

which, interchanging the order of integration and changing variables, can be written as

$$R_0 = \varphi(p) = \frac{hK}{(e + K)L} \int_0^{+\infty} \int_0^{+\infty} \pi(s + \tau)e^{-(\alpha+\sigma)\tau}$$

$$\times G' \left( \frac{\sigma}{\alpha + \sigma} + \frac{\alpha}{\alpha + \sigma}e^{-(\alpha+\sigma)\tau} \right) d\tau \, ds. \quad (23)$$

Finally, with further changes of the order of integration and of variables, one arrives at showing that $\varphi(p)$ and hence $\rho(B(-\mathcal{A}_l)^{-1})$ is given by the expression in (14). \qed

In order to give a biological interpretation of the quantity $R_0$ defined in the previous theorem, it is convenient to think in terms of the average number of infectious ‘parcels’ produced, in a population at the infection–free equilibrium, by one average infectious ‘parcel’ in absence of further infections.

By definition, at time $\tau = 0$, the ‘parcel’ will consist of $i$ parasites with probability $c_i$; then, it will be subject to a death-and-extinction process $Z(\tau)$, due to parasite deaths (at rate $\sigma$) and host deaths (at rate $\mu(a) + \alpha j$), if host’s age is $a$ and number of parasites is $j$. Assume that the initial host’s age (at time $\tau = 0$) is $a$. Then $p_i(\tau)$
(the probability that the host is alive and carries $i$ parasites at time $\tau$) satisfies the following system of equations:

$$
\begin{cases}
p_i'(\tau) = -\left(\mu(a + \tau) + i(\alpha + \sigma)\right)p_i(\tau) + \sigma(i + 1)p_{i+1}(\tau), \\
p_i(0) = c_i.
\end{cases}
$$

(24)

Analogously to the above, considering the variables $q_i(\tau) := \frac{p_i(\tau)\pi(a)}{\pi(a + \tau)}$ and

$$
Q(\tau, z) := \sum_{i=0}^{+\infty} q_i(\tau) z^i,
$$

we find that $Q$ satisfies

$$
\begin{cases}
Q_\tau(\tau, z) + \left((\alpha + \sigma)z - \sigma\right)Q_z(\tau, z) = 0, \\
Q(0, z) = G(z).
\end{cases}
$$

(25)

The solution of (25) is

$$
Q(\tau, z) = G\left( e^{-\left(\alpha + \sigma\right)\tau}z + \frac{\sigma}{\alpha + \sigma}(1 - e^{-\left(\alpha + \sigma\right)\tau}) \right). 
$$

(26)

Furthermore, the average number of parasites surviving (together with the host) at time $\tau$ is

$$
E(Z(\tau)) = \sum_{i=1}^{\infty} ip_i(\tau) = \frac{\pi(a + \tau)}{\pi(a)} \sum_{i=1}^{\infty} iq_i(\tau) = \frac{\pi(a + \tau)}{\pi(a)} Q_2(\tau, 1)
= \frac{\pi(a + \tau)}{\pi(a)} G'\left( \frac{\sigma}{\alpha + \sigma} + \frac{\alpha}{\alpha + \sigma} e^{-\left(\alpha + \sigma\right)\tau} \right) e^{-\left(\alpha + \sigma\right)\tau}.
$$

(27)

Since the rate at which each parasite produces new successful infectious ‘parcels’ is (when the population density is $K$) $\frac{hK}{c + K}$ the average number of new successful parcels produced over all times $\tau > 0$ is

$$
R(a) = \frac{hK}{c + K} \int_0^{\infty} E(Z(\tau)) \, d\tau
= \frac{hK}{c + K} \int_0^{\infty} \frac{\pi(a + \tau)}{\pi(a)} G'\left( \frac{\sigma}{\alpha + \sigma} + \frac{\alpha}{\alpha + \sigma} e^{-\left(\alpha + \sigma\right)\tau} \right) e^{-\left(\alpha + \sigma\right)\tau} \, d\tau.
$$

(28)

We made explicit the dependence of the previous computations on the initial host’s age $a$.

We need now to consider an average infection. In a stationary population, the probability density of hosts’ age is $\frac{\pi(a)}{L}$. Hence, a natural definition for the reproductive number is

$$
R_0 = \int_0^{\infty} \frac{\pi(a)}{L} R(a) \, da.
$$

Substituting (28) in this expression, we obtain exactly expression (23) for $R_0$.

Finally, we consider the special case, already studied through 3-dimensional approximations, where no parameters are age-dependent and the distribution of infectious ‘parcels’ is a (truncated) Poisson.
Corollary 1. Let \( \mu(a) \equiv \mu \) for each \( a \in [0, +\infty) \), and \( c_i = \frac{\lambda_i e^{-\lambda_i}}{i! (1 - e^{-\lambda})} \) for \( i \geq 1 \). Then,

\[
R_0 = \frac{hK}{c + K} \frac{\lambda e^{-\lambda}}{1 - e^{-\lambda}} \frac{1}{\alpha + \sigma} \int_0^1 t^{\frac{\lambda}{\alpha + \sigma}} e^{\frac{\lambda}{\alpha + \sigma} t} dt.
\]

(29)

Proof. By Proposition 4.1

\[
R_0 = \frac{hK}{(c + K)L} \int_0^{+\infty} e^{-(\alpha + \sigma) a} G'(\frac{\sigma}{\alpha + \sigma} + \frac{\alpha}{\alpha + \sigma} e^{-(\alpha + \sigma) a}) da \int_0^{+\infty} \pi(a + s) ds.
\]

Since \( \mu(a) = \mu \), we have \( \pi(a + s) = e^{-\mu(a + s)} \) and \( L = \int_0^{+\infty} \pi(s) ds = \frac{1}{\mu} \). Moreover

\[
G(z) = \sum_{i=1}^{+\infty} \frac{z^i \lambda^i e^{-\lambda}}{i! (1 - e^{-\lambda})} = \frac{e^{-\lambda} (e^{\lambda z} - 1)}{1 - e^{-\lambda}} \text{ so that } G'(z) = \frac{\lambda e^{-\lambda}}{1 - e^{-\lambda}} e^{\lambda z}.
\]

Therefore, we have

\[
R_0 = \frac{hK}{c + K} \frac{\lambda e^{-\lambda}}{1 - e^{-\lambda}} \int_0^{+\infty} e^{-(\alpha + \sigma + \mu) a} e^{\lambda(\frac{\sigma}{\alpha + \sigma} + \frac{\alpha}{\alpha + \sigma} - (\alpha + \sigma) a)} da,
\]

which through a change of variables reduces to the form (29).

Remark 1. Note that in the 3-dimensional approximation of the same model [21], it was shown that

\[
R_0 = \frac{hK}{c + K} \frac{\lambda}{1 - e^{-\lambda}} \frac{1}{\mu + \sigma + \alpha + \eta_K},
\]

where \( \eta_K \) solves the second degree equation

\[
\eta(\sigma + \alpha + \eta + \frac{hK}{c + K} - \alpha hK) = 0.
\]

It is then apparent that this approximation does not yield the correct threshold parameter (29).

In order to interpret (29), it is first of all worth noting that \( \frac{\lambda}{1 - e^{-\lambda}} \) is the average number of parasites per clump, so that, when \( \lambda \) goes to 0, we recover the model with single infections. Consistently, it is easy to see that, setting \( \lambda = 0 \) in (29), we obtain the expression (1).

Since \( h \) is the rate at which parasite clumps are produced and released from adult parasites, and \( \frac{\lambda}{1 - e^{-\lambda}} \) is the average number of parasites per clump, it is convenient to use the parameter \( h' = h \frac{\lambda}{1 - e^{-\lambda}} \), which represents the rate at which new infecting parasites are produced. Then we can write

\[
R_0 = \frac{h' K}{c + K} \frac{1}{\alpha + \sigma} \int_0^1 t^{\frac{\lambda}{\alpha + \sigma}} e^{\frac{\lambda(t + 1)}{\alpha + \sigma}} dt.
\]

(30)

This expression is decreasing in \( \lambda \), which shows that infections in clumps have a negative effect on the reproduction number \( R_0 \). If parasite aggregation were caused by 'clumped' infections, increasing aggregation would reduce the reproduction number, and so the persistence, of parasites, in contrast with the conclusions obtained in the 2–dimensional approximation [1].

Finally, since (30) is still a complex expression, some approximations may be useful. Here, in particular, we consider the cases of \( \alpha \) close to 0 (little mortality induced by parasites) and \( \lambda \) close to 0 (small clumps).
For the first case, one easily obtains
\[ R_0 = \frac{h'K}{c + K} \frac{1}{\mu + \sigma} \left( 1 - \alpha \left( \frac{1}{\mu + \sigma} + \frac{\lambda}{\mu + 2\sigma} \right) + O(\alpha^2) \right), \quad (31) \]
while for the second
\[ R_0 = \frac{h'K}{c + K} \frac{1}{\mu + \alpha + \sigma} \left( 1 - \frac{\alpha \lambda}{\mu + 2(\alpha + \sigma)} + O(\lambda^2) \right). \quad (32) \]
Both (31) and (32) clearly quantify the negative effect of \( \lambda \) on the basic reproductive number \( R_0 \).
